Name: 湯嘉為

▼ Question 1 (100 points)

Implementing Trie in Python.

Trie is a very useful data structure. It is commonly used to represent a dictionary for looking up words in a vocabulary.

For example, consider the task of implementing a search bar with auto-completion or query suggestion. When the user enters a query, the search bar will automatically suggests common queries starting with the characters input by the user.

按兩下 (或按 Enter 鍵) 即可編輯

```
# YOUR CODE HERE!
# IMPLEMENTIG TRIE IN PYTHON

class TrieNode:

    def __init__(self, char):
        self.char = char
        self.children = {}
        self.finished = False
        self.counter = 0

class Trie(object):

    def __init__(self):
        self.root = TrieNode("")

    # def insert(self, word):
    def insert(self, word):
        node = self.root
        for char in word:
            if char in node.children:
                node = node.children[char]
            else:
                new_node = TrieNode(char)
                node.children[char] = new_node
                node = new_node
        node.finished = True
        node.counter += 1

    # def dfs(self, node, prefix):
    def dfs(self, node, prefix):
        if node.finished:
            self.output.append((prefix + node.char, node.counter))

        for child in node.children.values():
            self.dfs(child, prefix + node.char)

    # def query(self, x):
    def query(self, x):
        self.output = []
        node = self.root
        for char in x:
            if char in node.children:
                node = node.children[char]
            else:
                return []

        self.dfs(node, x[:-1])
        return sorted(self.output, key=lambda x: x[1], reverse=True)

# # DO NOT MODIFY THE VARIABLES
```

```
obj = Trie()
obj.insert("長庚資工")
obj.insert("長大")
obj.insert("長庚")
obj.insert("長庚")
obj.insert("長庚大學")
obj.insert("長庚科技大學")

# # DO NOT MODIFY THE BELOW LINE!
# # THE RESULTS : [(words, count), (words, count)]
print(obj.query("長"))
# [('長庚', 2), ('長庚資工', 1), ('長庚大學', 1), ('長庚科技大學', 1), ('長大', 1)]

print(obj.query("長庚"))
# [('長庚', 2), ('長庚資工', 1), ('長庚大學', 1), ('長庚科技大學', 1)]
    [('長庚', 2), ('長庚資工', 1), ('長庚大學', 1), ('長庚科技大學', 1), ('長大', 1)]
    [('長庚', 2), ('長庚資工', 1), ('長庚大學', 1), ('長庚科技大學', 1)]
```
